

rigorous stocks assessments and marine surveys. Accordingly, President George W. Bush has requested an increase of \$8.9 million to NOAA's \$31.6 million budget next year for fishery assessments, and Congress seems amenable to the hike. But Hilborn doubts that amount would be nearly enough. "To do it right would take a staggering increase in resources," he says.

Another regulation will give NMFS

more data on recreational fishing, which can rival the impact of commercial fishing in some parts of the country, by creating a registry of saltwater anglers. The agency will accept public comments through 11 August, and the catch-limit rule remains open for public comment until 8 September. The agency hopes to finalize both rules by the end of the year.

FUSION REACTOR

ITER Costs Give Partners Pause

Last week, ITER scientists revealed a new cost estimate for the multibillion-dollar fusion reactor that was 30% higher than earlier calculations. Now the project's seven international partners must decide whether they can afford it.

ITER, or the International Thermonuclear Experimental Reactor, is designed to show conclusively that fusing together hydrogen isotopes at extreme temperatures—the process that powers the sun—can be harnessed on Earth as a practical energy source. Fifteen years of discussion and experiment led in 2001 to a "final" design for the 20,000-ton ITER reactor, twice the size in linear dimensions of the world's current largest. Since then, the partners—China, the European Union, India, Japan, Russia, South Korea, and the United States—have chosen Cadarache in southern France as a site and set up the organization that will build the reactor (*Science*, 13 October 2006, p. 238).

The current price tag is €10 billion, half of which will pay for construction. Last week, the project's governing council met in Aomori, Japan, to hear about a new review of that 2001 design that includes numerous refinements and upgrades to components, including magnets and heating systems, plus additional magnets to help control explosive discharges at the plasma edge (*Science*, 13 June, p. 1405). Those design changes will cost an extra €1.2 billion to €1.6 billion, ITER managers estimate, and the council immediately ordered an independent assessment of the costs in time for its next meeting in November. In the meantime, the council did approve a 2-year delay, to 2018, in the expected start-up of the reactor.

Fusion experts say that it's notoriously hard to keep such large projects within budget. "When they actually go out and build things, they always cost more," says Stephen Dean, president of Fusion Power Associates, a lobby group in Gaithersburg, Maryland. But

ITER scientists believe that the design changes are crucial to the project's chance of success and that the partners should approve the new cost estimate. "It will define what we can do and when we can do it," says David Campbell, assistant head of ITER's department of fusion science and technology. It won't be an easy sell, however: Some

Going up. As ITER's partners prepare to start construction, design changes are bumping up the cost.

ITER partner governments won't be happy at being asked to fork out more.

The panel tasked with assessing the new cost estimate will be led by Frank Briscoe, former operations director of the JET fusion reactor near Oxford, U.K. The European Union, which as host must bear nearly 50% of the cost, declined comment on the new estimate beyond saying, in the words of research spokesperson Catherine Ray, that "we're happy [Briscoe's] group has been set up." Meanwhile, the partners in the world's most expensive experiment will be debating its future. "There will be some very, very hard diplomatic negotiations over what the partners are prepared to pay," says a senior European researcher who asked not to be named.

Hungary: Where Europe Will Be EITing

Budapest will host the headquarters of the new European Institute of Innovation and Technology (EIT). Conceived as a way to boost innovation à la the Massachusetts Institute of Technology, EIT has been roundly criticized by European scientists as misconceived and politically motivated (*Science*, 21 September 2007, p. 1676). But József Pálkás, president of the Hungarian Academy of Sciences, says he hopes EIT will attract new investors to the region and inspire Hungary's students and young scientists. "It shows that Hungary is a player" in the European science scene, he says.

Hungary beat out Wrocław, Poland; Jena, Germany; the Spanish city of Sant Cugat des Vallés; and a twin bid by Vienna, Austria, and Bratislava, Slovakia, for the right to host the administrative headquarters of the virtual institute, which is slated to receive €300 million through 2013.

Council: Machine Won't Destroy Earth

With only weeks to go before particles begin whizzing around in the Large Hadron Collider (LHC), the world's most powerful particle accelerator, at CERN near Geneva, Switzerland, the lab's governing council sought last week to get one thing straight: Yes, it's safe. Honest.

Citing some of the more exotic theories of fundamental physics, online commentators have suggested that the LHC's particle collisions could create a microscopic black hole that, if stable, could swallow up Earth. Other potential threats include vacuum bubbles, magnetic monopoles, and strangelets. Two people even filed a lawsuit in U.S. federal court in Hawaii in March to try to halt LHC operations until a safety and environmental audit is carried out.

Although the lab looked into the issue in 2002, media interest in the perceived risks and new results and theories in physics drove the lab to reexamine it. CERN's 15-page report, released last week, concluded that "there is no basis for any concerns," principally because thousands of cosmic rays with energies much higher than LHC can achieve bombard Earth every day, yet no black hole or exotic particle has yet devoured the planet. "The Web has become a place where people can steer the scientific process in unpredictable ways," says CERN theorist Michelangelo Mangano, a co-author of the new report.
